

On intersection probabilities of four lines inside a planar convex domain

Abstract

Let $n \geq 2$ random lines intersect a planar convex domain D . Consider the probabilities p_{nk} , $k=0,1,\dots,n(n-1)/2$ that the lines produce exactly k intersection points inside D . The objective is finding p_{nk} through geometric invariants of D . Using Ambartzumian's combinatorial algorithm, the known results are instantly reestablished for $n=2,3$. When $n=4$, these probabilities are expressed by new invariants of D . When D is a disc of radius r , the simplest forms of all invariants are found. The exact values of p_{3k} and p_{4k} are established.
